Notational Matter:

$$f(x|\eta) = \frac{A(\eta) h(x) \exp\left(\sum_{j=1}^k \eta_j T_j(x)\right)}{C(\eta)}$$

Recall Example  $N(\mu, \sigma^2)$ 

$$f(x|\mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp(\eta_1 x^2 + \eta_2 x) \exp\left(-\frac{\mu^2}{2\sigma^2}\right)$$

$$T_1(x) = x^2 \quad T_2(x) = x \quad \eta_1 = -\frac{1}{2\sigma^2} \quad \eta_2 = \frac{\mu}{\sigma^2}$$

We can thus see that for  $X_1, \dots, X_n$  iid  $N(\mu, \sigma^2)$  the natural sufficient statistic is  $T(X) = (\sum X_i^2, \sum X_i)$  and we can apply the exponential family stuff to conclude that  $T(X)$  is minimal sufficient

$$\eta(\mu, \sigma^2) = (\eta_1(\mu, \sigma^2), \eta_2(\mu, \sigma^2))$$

$E_{\text{Ⓢ}}$  is a half plane and contains an open set — one thing this implies is that  $T(x)$  is minimal sufficient

---

??? What does this requirement for  $E_{\text{Ⓢ}}$  to contain an open set intend to exclude???

To think about this, consider two sub-models of the  $N(\mu, \sigma^2)$  model ...

- 1)  $N(\mu, 1)$
- 2)  $N(\mu, \mu^2)$

Example  $N(\mu, 1)$

$$f(x|\mu) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}x^2 + \underset{\substack{\downarrow \\ \eta}}{x\mu} - \frac{\mu^2}{2}\right)$$

with  $\eta = \mu$  we have a 1-dimensional exponential family ... for iid observations The natural sufficient statistic is

$$T(X) = \sum X_i \quad \mathbb{R}^1$$

and since  $\mathcal{E} \ni \text{(or } \textcircled{+})$  contains an open rectangle This is minimal sufficient

Relation to full  $N(\mu, \sigma^2)$  model >

$$\eta_1 = -\frac{1}{2}$$

$$\eta_2 = \mu$$

$$\mathcal{R}^1 = \mathbb{H}$$

$X_1, \dots, X_n$  iid

$$T(X) = (\sum X_i^2, \sum X_i)$$

sufficient

I can't use the exponential family machinery to conclude  $(\sum X_i^2, \sum X_i)$  is minimal sufficient -

has no interior in  $E \subset \mathbb{R}^2$

Example  $N(\mu, \mu^2)$

$$f(x|\mu) = \frac{1}{\sqrt{2\pi}|\mu|} \exp\left(-\frac{1}{2\mu^2}x^2 + \frac{x}{\mu} - \frac{1}{2}\right)$$

$\eta_1(\mu)$  points to  $-\frac{1}{2\mu^2}$   
 $\eta_2(\mu)$  points to  $\frac{x}{\mu}$

with

$$\eta_1(\mu) = -\frac{1}{2\mu^2} \quad \eta_2 = \frac{1}{\mu}$$

$$T_1(x) = x^2 \quad T_2(x) = x$$

This is some sort of exponential family  
 with  $X_1, \dots, X_n$  the natural sufficient  
 statistic is

$$T(X) = \left( \sum X_i^2, \sum X_i \right)$$

But...  $\mathcal{L}_1$  is really only "1-dimensional"  
and so also is the set  $\eta = (\eta_1, \eta_2)$  that I  
can get to from  $\mathcal{L}_1$

$\mathcal{L}_1 \subset \mathbb{R}^1$

note that  $\eta_1 = -\frac{1}{2}\eta_2^2$

this has no  
interior in  $\mathcal{E}$

?? Is  $(\sum X_i^2, \sum X_i)$  minimal sufficient

This is an example of a "curved exponential family" -  $\exists$  Theory for such families

Begin reading ch 2 - The topic is  
"Estimation"

The basic idea is to use  $X$  to guess at  
the value of  $\theta$  or some function of  $\theta$ , say  
 $\gamma(\theta) \in \mathbb{R}^k$

Def A statistic  $S(X)$  taking values in  
 $\gamma(\Theta)$  (range of  $\gamma$ ) is called a point  
estimator of  $\gamma(\theta)$

Standard Examples

$X_1, X_2, \dots, X_n$  iid  $N(\mu, \sigma^2)$

$\delta(X) = (\bar{X}, S^2)$  is an obvious point estimator of  $(\mu, \sigma^2)$

(? What about  $\delta(\mu, \sigma^2) = \Phi\left(\frac{17-\mu}{\sigma}\right)$ ??  
How to guess at this?)

②  $X_1, X_2, \dots, X_n$  iid Bernoulli  $p$   
 $\delta(X) = \frac{\sum X_i}{n}$  is an obvious point estimator of  $p$

(? What about,  $\delta(p) = p^2$ ? How to approximate?)
