Recall: 3rd piece of optimality theory for point estimation ... Cramér-Rao Inequality (based on "Fisher Information") ... Handout for  $\Theta \subset \mathbb{R}^k$  and technical details ...

$L(\theta)$  likelihood

$l(\theta) = \log L(\theta)$  loglikelihood

score function =  $l'(\theta) = \frac{d}{d\theta} l(\theta)$

Note:  $E_{\theta_0} l'(\theta_0) = E_{\theta_0} \left. \frac{d}{d\theta} \log f(X|\theta) \right|_{\theta=\theta_0}$

cont's case

$$\textcircled{=} \int \frac{\left. \frac{d}{d\theta} f(x|\theta) \right|_{\theta=\theta_0}}{f(x|\theta_0)} f(x|\theta_0) dx$$

$$= \int \left. \frac{d}{d\theta} f(x|\theta) \right|_{\theta=\theta_0} dx$$

AIP

$$\textcircled{=} \left. \frac{d}{d\theta} \int f(x|\theta) dx \right|_{\theta=\theta_0}$$

$$= \left. \frac{d}{d\theta} 1 \right|_{\theta=\theta_0}$$

$\theta_0$   
The mean of the score function at  $\theta_0$  is 0 -

on  $(\theta_0)$  average The log-likelihood is "flat" at  $\theta_0$

The happiest circumstance is that when the (random)  $l'(\theta_0)$  is big in magnitude ... Why? because that says that the loglikelihood is climbing sharply at  $\theta_0$  or is dropping sharply at  $\theta_0$  i.e. values close to  $\theta_0$  are distinguished ... so I want big

$$E_{\theta_0} (l'(\theta_0))^2$$

$$E_{\theta_0} (l'(\theta_0))^2 = \mathbb{I}_X(\theta_0) = \text{Var}_{\theta_0} l'(\theta_0)$$

is the Fisher Information in  $X$  about  $\theta$  at  $\theta_0$   
 (The multidimensional version of this is that  
 the  $k \times k$  Fisher Information matrix is the variance-covariance matrix of the score function)

Example  $X \sim \text{Bi}(n, p)$

$$L(p) = \binom{n}{x} p^x (1-p)^{n-x}$$

$$l(p) = \log \binom{n}{x} + x \log p + (n-x) \log(1-p)$$

$$l'(p) = \frac{x}{p} - \frac{n-x}{1-p}$$

$$E_{p_0} l'(p_0) = \frac{np_0}{p_0} - \frac{n - np_0}{1 - p_0} = 0$$

$$\begin{aligned} \mathcal{I}(p_0) &= E_{p_0} (l'(p_0))^2 \\ &= \text{Var}_{p_0} \left[ X \left( \frac{1}{p_0} + \frac{1}{1-p_0} \right) - \frac{n}{1-p_0} \right] \\ &= \left( \text{Var}_{p_0} X \right) \left( \frac{1}{p_0(1-p_0)} \right)^2 \\ &= \frac{n}{p_0(1-p_0)} \end{aligned}$$

To your collection of plots for the  $\text{Bi}(5, p)$  problem you could add a plot of  $\mathcal{I}(p)$

$$I(p) = \frac{5}{p(1-p)}$$

There are a number of useful simple results about FI

Result Under appropriate regularity conditions

$$I(\theta_0) = -E_{\theta_0} (l''(\theta_0))$$

The information in  $X$  about  $\theta$  evaluated at  $\theta_0$  is not only the  $\theta_0$  variance of the score function evaluated at  $\theta_0$ , it is also the  $\theta_0$  expected curvature of

the log likelihood at  $\theta_0$  — The curved The  
 loglikelihood tends to be, the more discriminating  
 is the loglikelihood and the better is one's information  
 about  $\theta$

"Pf" Outline for the conts case

$$l''(\theta) = \frac{d}{d\theta} \left( \frac{\frac{d}{d\theta} f(x|\theta)}{f(x|\theta)} \right)$$

$$= \frac{f(x|\theta) \frac{d^2}{d\theta^2} f(x|\theta) - \left( \frac{d}{d\theta} f(x|\theta) \right)^2}{(f(x|\theta))^2}$$

$$\text{So } E_{\theta_0} l''(\theta_0) = \int \frac{d^2}{d\theta^2} f(x|\theta) \Big|_{\theta=\theta_0} dx$$

AIP

$$- \int \frac{\left( \frac{d}{d\theta} f(x|\theta) \Big|_{\theta=\theta_0} \right)^2}{(f(x|\theta_0))^2} f(x|\theta_0) dx$$

$$\stackrel{\text{②}}{=} \frac{d^2}{d\theta^2} \int f(x|\theta) dx \Big|_{\theta=\theta_0} - \int \left( \frac{d}{d\theta} \log f(x|\theta) \Big|_{\theta=\theta_0} \right)^2 f(x|\theta_0) dx$$

$$= 0 - I(\theta_0)$$

$E_{\theta_0} (l'(\theta_0))^2$
